I. INTRODUCTION

Triennially, the Public Health Statistics Branch produces a major publication describing North Carolina's mortality experience for a five-year period. Those volumes include mapped, tabular and trend data as well as narrated analyses for leading causes of death in the state's 100 counties. In the interim, supportive reports of the mapped and tabular data are published annually.

The present volume is a supportive report which may be used in conjunction with the 1972-76 publication for purposes of current health planning and analysis. The Public Health Statistics Branch will also continue to publish the report <u>Detailed Mortality Statistics</u> which provides annual counts of deaths classified according to underlying causes of death and the age, race and sex of decedents.

The tables of this report provide selected mortality statistics for counties, Department of Human Resources Regions, Health Service Areas, and the state (see maps on preceding pages). More than a dozen of North Carolina's leading causes of mortality are depicted in these tables and corresponding maps; in addition, various cancer sites are also tabled and mapped. Total infant mortality data are shown in Table 28 and Figure 28, and Table 1 on page 13 describes the cause of death categories in terms of codes from the International Classification of Diseases, Adapted.

Beginning with 1975 events, multiple conditions present at death are being coded such that we now have statistics relative to underlying causes of death (Tables 1-27 and corresponding Figures) as well as all conditions present at death and reported by the certifier (Tables 29 and 30). Three diseases in particular—hypertension, arteriosclerosis and diabetes—are considered associated conditions far more often than they are considered an underlying cause; hence, Figures 29.A-31.B display 1975-77 county rates for deaths associated with a mention of each of these diseases. Series A maps (black) are observed rates while series B maps (red) are age-race-sex-adjusted rates.

IN USING THIS VOLUME, PARTICULAR ATTENTION IS CALLED TO THE SECTION ON INTERPRETATION GIVEN ON PAGES 8 and 9.

II. NORTH CAROLINA MORTALITY TRENDS FROM 1973 THROUGH 1977

After reaching its highest peak in more than thirty years during 1972, North Carolina's general mortality rate declined between 1973 and 1975. From a 1973 rate of 9.0 deaths per 1,000 population, the 1975 death rate dropped to 8.4, where it remained through 1977. This rate is the lowest since 1962. While the decline involved both race groups, it was not shared equally by them. Nonwhites experienced the greatest percentage decline: 10% compared to 5% for whites.

The trend since 1968 marks an even greater decline among nonwhites. In 1968, the nonwhite mortality rate was 25% higher than the white rate; in 1973 it was 19% higher; and in 1977, 12% higher.

Although the gap between whites and nonwhites has diminished, the margin between North Carolina males and females remained wide. Males experienced a 41% higher mortality rate than females in 1973. In 1977, the male rate was 43% higher. The male death rate is not increasing; rather, the mortality rate for females is declining faster. From 1973 through 1977, the male rate decreased 6% from 10.6 to 10.0 per 1,000 population. At the same time, the rate for females declined 7% from 7.5 to 7.0.

Of the four race-sex groups, nonwhite males had the highest 1977 mortality rate (11.2) followed by white males (9.6), nonwhite females (7.4) and white females (6.8).

Not only have mortality rates recently declined for all race-sex groups but for all eight age groups studied as well. Whites have lower mortality rates than nonwhites in every age group. The 1977 nonwhite rate was approximately twice as high in the 0-4, 25-34, 35-44, and 45-54 age groups. The higher nonwhite rate in the 0-4 age group was compounded by a larger decline among whites of the same age during the period 1973-1977. However, for the six age groups from 5-14 to 55-64, the percentage decline in mortality rates was greater among nonwhites by substantial margins.

Of the 26 selected causes of death tabled in this volume, 18 reflect declining rates from 1973 to 1977. Heart disease, long the leading cause of death in the state and nation, declined about 6% from a rate of 326.3 per 100,000 population in 1973 to 306.4 in 1977. Cerebrovascular diseases, the third leading cause of death, declined 18% from a rate of 110.8 to 90.9. Deaths from motor vehicle accidents declined 27%, dropping from a 1973 rate of 35.7 to the 1977 rate of 26.1. This decline was largely the result of the 1974 decision to lower the maximum speed limit to 55 miles per hour.

The selected causes of death in this volume represent 86% of North Carolina's total resident mortality in 1977. Of these causes, only cancer, nephritis and nephrosis, and chronic obstructive lung disease have shown rate increases from 1973 to 1977.

Five of the nine cancer sites referenced in this volume showed mortality rate increases from 1973 to 1977. Those sites and their percentage increases were: colon and rectum, 22.0; lung cancer, 21.4; breast cancer, 15.2; prostate, 8.0; and pancreatic cancer, 4.9. These rate increases are distressing for several reasons. One is that cancer of the colon-rectum, prostate and breast are often detectable at routine health checkups. Another is that while lung cancer is not often detected early, most lung cancers could be prevented by improving health habits and working conditions, i.e., not smoking and eliminating pollution hazards.

Nephritis and nephrosis mortality involved a 24% rate increase from 1973 to 1977. The 1977 rate of 5.6 deaths per 100,000 population was the highest rate for this cause of death since 1967. Nonwhite males experienced both the highest rate and the largest percentage increase from 1973 to 1977. The rates for 1977 with corresponding percentage increases were as follows: nonwhite males 13.1 and 58%; nonwhite females 9.8 and 21%; white males 4.1 and 0%; white females 3.5 and 25%.

Looking at Table 1 (page 13), one sees that chronic obstructive lung disease increased 114% from 1973 to 1977. A large part of this increase is due to certification (terminology) preference. To obtain a better view of the actual increase, we combined deaths from bronchitis, emphysema and asthma with those from chronic obstructive lung disease over the 1973-77 period. The rate for the entire complex of chronic obstructive lung diseases

increased 19% from a 1973 rate of 16.2 to a 1977 rate of 19.3. The 1977 rates and percent change from 1973 for combined chronic obstructive lung diseases by race-sex groups were as follows: white males 35.0 and 20%; white female 10.5 and 27%; nonwhite males 16.5 and 28%; nonwhite females 2.3 and -50%. Thus, all race-sex groups experienced rate increases with the exception of nonwhite females who had the lowest rates in 1973 and then reduced that rate by half.

The importance of suicide as a leading cause of death is illustrated by the fact that it was the twelfth leading cause of death in 1973, but the eighth in 1977. However, this is not due to an increasing suicide rate; in fact, North Carolinians are killing themselves at the same rate as in 1973. Rather, the suicide rate has stabilized while mortality from most other causes has declined.

While the number of suicides in 1977 exceeded the 1973 number by only 30, a greater percentage of current suicides are by people under age 35. Specifically, 29% of all suicides in 1973 were by people under age 35 whereas the corresponding figure for 1977 was 37%.

Suicide rates differ markedly among the four race-sex groups. In 1977, white males had the highest rate of 23.8 deaths per 100,000 population; nonwhite males were second at 10.5; white females at 7.5 were third, and nonwhite females were least likely to take their own lives with a rate of 2.2.

To compare suicide rates of the different age-race-sex groups, see the table on the next page. Although the 1977 white suicide rate of 15.4 was more than twice the nonwhite rate of 6.1, the percentage of suicide victims under age 35 was far greater for nonwhites (55%) than for whites (35%).

Even though North Carolina's 1977 infant death rate of 15.8 (infant deaths per 1,000 live births) marked a decline of 27% compared to its 1973 rate of 21.7, only three states and the District of Columbia had higher infant mortality rates than North Carolina in 1976. In North Carolina, nonwhites had an infant mortality rate almost twice that of whites in 1977, 23.3 vs. 12.2. Males had higher infant mortality rates than females, 17.9 vs. 13.6. Although all race-sex groups experienced infant mortality declines since 1973, the percent declines for nonwhites and males have not kept pace with those for whites and females. The state's 1977 infant death rates by race-sex groups are listed with their percent decline since 1973: white males 13.9 and 28%; white females 10.4 and 38%; nonwhite males 26.4 and 18%; nonwhite females

III. MORTALITY RATES

Computation

In this report, general mortality rates are expressed as resident deaths per 1,000 population while all cause-specific mortality rates are expressed as resident deaths per 100,000 population. The infant mortality rates of Table 28 and Figure 28 are computed as the number of resident infant deaths per 1,000 resident live births.

North Carolina rules for determining decedent's residence specify that place of residence during military duty or during attendance at college is the military or college community. For deaths in hospitals, sanatoria, and other institutions (mental, penal, nursing home, etc.), the usual residence prior to admission to the institution is given. In contrast to this, the Census enumerates long-term institutionalized persons as residents of the area where the institution is located.

The following definitions apply to the rates of Tables 1-27:

Annual Death Rate: the annual death rate computed as resident deaths per 1,000 or 100,000 population. These rates permit the user knowledge of an area's status with respect to the observed incidence of mortality during the given year.

5-Year Death Rate: the average annual death rate computed as average resident deaths per 1,000 or 100,000 average population. These rates permit the user knowledge of an area's status with respect to the observed incidence of mortality during the 5-year period. These rates are depicted in the Series A maps printed in black.

5-Year Adjusted Death Rate: the average annual age-race-sex-adjusted rates, computed by the direct method. Also expressed as deaths per 1,000 or 100,000 population, these rates are those which would be expected if the average annual age, race and sex composition of each county's population were the same as that estimated for the state. These rates are free of the effects of age, race and sex and thus permit the user knowledge of an area's status with respect to other determinants of mortality during the 5-year period. These rates are depicted in the Series B maps printed in red.

Population bases for the rates of this report were provided by the Office of State Budget and Management of the North Carolina Department of Administration. For the maps, we clustered counties into six rate intervals using the Statistical Analysis System to group counties "most like each other."

Interpretation

To assess an area's relative mortality conditions during a five-year period, both the observed rate and the adjusted rate can be compared to the state rate for a particular cause of death. Then, provided the area's observed rate represents a relatively stable situation, viz., the rate has not fluctuated widely in recent years, the following alternative diagnoses will apply:

Relative Observed Rate	Status of Adjusted Rate	Diagnosis
Low	Low	Low mortality is not due to age, race and sex factors; other mortality conditions are favorable.
Low	High	Low mortality is due to favorable age, race and sex factors; other mortality conditions are unfavorable.
High	Low	High mortality is due to unfavorable age, race and sex factors; other mortality conditions are favorable.
High	High	High mortality is not due to age, race and sex factors; other mortality conditions are favorable.

Caution!

In assessing the relative mortality conditions of a county, one should be particularly aware of small numbers since, in such cases, random fluctuation in the rate may render rate comparisons invalid. This is the case in Mitchell County where there are few nonwhites and a single nonwhite death can drastically alter the county's death rate. To illustrate, one 1977 death in an age-race-sex population group estimated at only 1 resident contributed to the county's age-race-sex-adjusted nephritis/nephrosis death rate rising from 2.16 during 1972-76 to 126.09 during 1973-77. Similarly, the county's adjusted cirrhosis death rate fell from 217.41 during 1972-76 to 3.30 during 1973-77 due to a non-white death during 1972. Other counties should be aware of similar situations.

Also, all counties should be aware that some maps for 1973-77 look quite different from corresponding maps for 1972-76. Although extensive changes

between two closely overlapping time periods generally would not be expected, it is recalled that death rates ran high in 1972 (9.0 for the state) compared to 1977 (8.4 for the state). The effect of deleting 1972 while adding 1977 served to alter clustering patterns more than usual. Depending on the 1978 experience, we may again see considerable change between 1973-77 and 1974-78 since rates also ran high during 1973 (9.0 for the state).

*Numbers shown here are the final underlying frequencies. They are sometimes larger than numbers shown on the Assonal due to the fact that a sequence of conditions may imply an underlying cause that is not specifically mentioned on the death certificate.

^{**}Differences between these totals and the summation over causes are attributable to causes not given in the table.

NOTE: In this table, a death is counted only once in a condition category although several conditions within the caspory may have been reported or a single condition may have been recorded more than once on the death cettlifeste.
